SecAI-TEST-en-short

When a small or medium-sized business detects unusual activity on its network, the incident response team must follow a five-step process: identification, containment, eradication, recovery, and lessons learned. During identification, administrators collect logs from the firewall, web server, and intrusion detection system to confirm whether this is a real incident or merely a false alarm. All initial evidence, including timestamps, source IP addresses, and related accounts, must be preserved intact before making any changes to the affected system.
